

1 Neuroprotective effects of tibolone 2 during astrocytic metabolic 3 inflammation: a network based 4 approach

5 Abstract:

6 1.1. Introduction

7 Astrocyte-Neuron Metabolic Relationships

8 Astrocytes are the most abundant cells in the human brain and play important roles in
9 the central nervous system (CNS) [1]. They are highly associated to several homeostatic fun-
10 ctions such as glutamate, ion, and water homeostasis, energy storage in the form of glycogen,
11 synapse formation and remodeling, defense against oxidative stress, scar formation, tissue
12 repair and modulation of synaptic activity via the release of gliotransmitters [2]. Astrocytes
13 metabolize glucose in anaerobic way to produce lactate, which is released to neurons through
14 monocarboxylate transporters [3]. Lactate is used in neurons as an energy substrate after
15 its conversion to pyruvate and subsequently to ATP via oxidative phosphorylation [4]. As-
16 trocytes play an important role in glutamate mediated synaptic activity [5]; according to the
17 astrocyte–neuron lactate shuttle model, astrocytes respond to glutamate induced activation
18 by increasing their rate of glucose uptake and the release of lactate into the extracellular spa-
19 ce, increasing the lactate available to be used by neurons to supply their energetic needs [6].
20 Glutamate is uptaked by astrocytes through the glutamate aspartate transporter and glial
21 glutamate transporter-1, inducing events that involves the activation of $\text{Na}^+\text{--K}^+\text{--ATPase}$
22 and maintaining extracellular glutamate at homeostatic levels [7]. Part of incorporated glu-
23 tamate is converted to glutamine through glutamine synthetase, which is only associated to
24 glial cells and released to neurons using electroneutral systems-N transporters coupled to
25 Na^+ and H^+ [8]. In neurons glutaminase enzyme converts glutamine back into glutamate
26 which can be used again for neurotransmission or metabolized into the neuronal Krebs cycle
27 [9]. Astrocytes release many other substances related to synaptic transmission [10]. However
28 D-serine, a neurotransmitter that act as a coagonist with glutamate at NMDA receptors

is one of the most important [5]. Due only glial cells can synthesize serine, all available D-serine at synapsis is associated to be primarily produced and secreted by astrocytes [8]. D-serine is synthesized in astrocytes by serine racemase from L-serine [11]. Additionally to these energy and synaptic support associated functions, astrocytes also play an important role in the reduced glutathione (GSH) metabolism of the brain [12]. GSH is the major cellular antioxidant and plays an important neuroprotective role [13]. Cellular GSH levels are closely correlated with cell survival under adverse conditions [14]. GSH is synthesized from glutamate, cysteine, and glycine and release directly from Astrocytes through GSH transporters ion-independent; GSH net transport is concentration-gradient dependent [15]. This strong metabolic cooperation between astrocytes and neurons allows to predict that even an small astrocytic dysfunction might cause and/or contribute neurodegenerative processes. Proper astrocyte function is fundamental for neuronal survival after different brain insults, such as inflammation, glucose deprivation, traumatic brain injury and ischemia. Astrocytes protect neurons of the most important factors that contribute to neuronal cell death such as glutamate-mediated excitotoxicity leading to disturbances in intracellular calcium and sodium metabolism, mitochondrial dysfunction, oxidative stress, cytokines and toxins.

Astrocytes response to Inflammation

Inflammation is a complex biological response to injuries, metabolic disorders or infections and its dysregulation induce many complex diseases through astrocytic dysfunction [13, 16, 17]. In brain, inflammatory response acts as a defense mechanism against any threat to homeostatic state inducing changes in glucose metabolism and release of proinflammatory factors [14]. Inflammation responses in CNS are mediated by glial cells that acquire reactive phenotypes to participate in repair mechanisms [1, 13, 18]. Astrocytes, as glial cells are highly sensitive cells to inflammatory mediators, they respond to inflammation through a complex reaction named astrogliosis [19]. During astroglyosis, glial cells generally associated to several beneficial activities in the CNS, also act as a source of inflammatory mediators and as generators of reactive oxidant species (ROS) that have the potential to damage neurons [20]. Astrogliosis is characterized by a low regulation of mitochondrial dynamics that result in mitochondrial failure [21]. Mitochondrial failure induces the deregulation of Ca^{2+} homeostasis and increased ROS generation, both of which are linked to neurotoxicity [2]. At metabolic level, inflammatory process has been associated to an increase of free saturated fatty acid in comparison with healthy conditions in some brain tissues [22]. The increase of free saturated fatty acid induce metabolic inflammation, a response associated with the induction of diverse intracellular stresses, such as mitochondrial oxidative stress, ER stress, and autophagy defects [13]. Lipid excess in metabolic inflammation activates hypothalamic $\text{IKK}\beta$ and $\text{NF-}\kappa\beta$ signaling pathways, which ultimately impairs hypothalamic leptin and insulin signaling and further triggers the synthesis and release of increased amounts of ROS and proinflammatory cytokines ($\text{TNF-}\alpha$ and IL-6) from glial cells to sustain the neuroinflammatory state [23].

Enhanced ROS generation by reactive glial cells trigger mitochondria dysfunction in neuron, which induces neuronal apoptosis, the prerequisite for a diverse number of neurodegenerative conditions [24].

Systems Biology and Inflammation

Inflammatory pathways are evolutionarily conserved, complex, redundant and interconnected. These characteristics difficult each attempt to understand any disease having inflammation at its core using the traditional reductionism-based scientific method and the current regulatory framework. Traditional methods generally focus on single molecules and genes as the targets of study and potential therapy development, nevertheless mechanistic simulation through a translational systems biology framework allows lead to an understanding of the origin of patterns in omic data in order to facilitate the design of novel therapies. Inflammation is a complex system, which is characterized by sensitivity to initial conditions, positive and negative feedback loops, combined robustness and fragility, and emergence of nonintuitive behaviors. Translational Systems Biology to inflammation is focused on simulated clinical trials, trying to progress toward personalized diagnostics, personalized medicine, and the rational design of drugs.

Tibolone

Steroids compounds are the most potent and effective agents in controlling chronic inflammatory diseases. However, steroids prescription is limited due their side adverse effects. Some steroids synthesized in the nervous system, called ‘neurosteroids’, display beneficial neuroprotective properties, which may be of particular importance in the treatment of diseases where neurodegeneration is predominant including age-dependent dementia, stroke, epilepsy, spinal cord injury, Alzheimer’s disease (AD) and Parkinson’s disease (PD). Tibolone is a synthetic steroid drug with estrogenic, progestogenic, and weak androgenic actions. Tibolone is metabolized in three compounds, two major active metabolites, 3α -hydroxytibolone and 3β -hydroxytibolone acting as potent agonists of the estrogen receptor (ER) and its metabolite $\Delta 4$ -tibolone acting as agonists of the progesterone and androgen receptors. Tibolone and their metabolites have tissue selective action mechanisms (progestogenic, androgenic and estrogenic) reported in liver, bone, breast and brain according to their receptor interaction and activation. Tibolone has been shown neuroprotective effects

In this work we simulate the metabolic inflammatory response caused by the increase uptake of palmitate, the most common free saturated fatty acid in healthy mature astrocytes. We model and simulate the metabolic response using a translational system biology approach called Flux Balance Analysis (FBA) described in methods. We focused in identification of changes in metabolic pathways activation, functional products, gliotransmitter release and the neuroprotective effects mediated by tibolone in an inflamed scenario.

103 1.2. Material and Methods

104 Tissue Specific Model Construction

105 The tissue specific model construction process started with the identification of all enzyme-
106 coding genes expressed over the mean in at least 50 % of samples for healthy human astrocy-
107 tes indexed in the GEO database [25] as GSE73721 [26]. Gene identifiers conversion from
108 GeneCards[27] to ENTREZ [28] was performed through ‘UniProt.ws’ R Package [29]. Reac-
109 tions associated with the identified genes were mapped from the Human Genome Scale Me-
110 tabolic Reconstruction RECON 2.04 downloaded from the VMH Lab (<https://vmh.uni.lu>)
111 [30]. The R package ‘g2f’ [31] was used to identify and fill the gaps using all no gene as-
112 sociated reactions included in RECON 2.04, as well as to identify and remove all blocked
113 reactions from the reconstruction. All reactions involved in the conversion of extracellular
114 glutamate, glycine, cysteine and glucose to extracellular glutamine, glycine, serine-D, redu-
115 ced glutathione, lactate and ATP respectively were added. Exchange reactions were limited
116 to components of the Dulbecco’s Modified Eagle Medium (DMEM) as input and gliotrans-
117 mitters (glutamine, D-serine, ATP, glutamate), reduced glutathione, lactate, glucose, nitric
118 oxide, prostaglandins and leukotrienes as output. Finally, syntax, mass-charge validation and
119 creation of SBML files were carried out through the ‘minval’ R Package [32]. Reaction limits
120 (upper and lower bounds) were constrained proportional to the mean gene expression repor-
121 ted for genes included in Gene-Protein-Reaction (GPR) [33] associated to each reaction in
122 samples of 47 to 63 years old using ‘exp2flux’ R package [34]. All analysis were done by the
123 ‘sybil’ [35] R Package running under R 3.3.1 [36].

124 Flux Balance Analysis

125 Flux Balance Analysis (FBA) is a linear optimization method for simulating metabolism that
126 allows to identify the set of reactions involved in the production of a biological response within
127 a metabolic model [37]. The metabolic reactions are represented internally as a stoichiometric
128 matrix (S), of size $m * n$, where m represents the compounds and n the reactions; the entries
129 in the matrix are the stoichiometric coefficients of the metabolites participating in a reaction
130 [38]. The flux through all of the reactions in a network is represented by the vector v , which
131 has a length of n . The concentrations of all metabolites are represented by the vector x , with
132 length m . The systems of mass balance equations at steady state, $\frac{d_x}{d_t} = 0$ or $S * v = 0$. FBA
133 seeks to maximize or minimize an objective function which can be any linear combination
134 fluxes, to obtain a flux for each reaction, indicating how much each reaction contributes
135 to the objective function [37]. FBA for healthy, inflamed and medicated scenarios was
136 resolved using GLPK 4.60, setting the generic human biomass reaction included in RECON
137 2.04 and each one of reactions described in table 1-1 as objective functions. Models were
138 analyzed by comparing fluxes between scenarios, metabolites production rate and sensitivity

139 analysis.

Table 1-1: Main metabolic capabilities associated to astrocytes represented as the set of objective functions used to evaluate neuroprotective effects of Tibolone under inflamed scenarios

ID	FORMULA REACTION	DESCRIPTION
Glu2Gln	1 glu_L[e] \Rightarrow 1 gln_L[e]	Glutamate - Glutamine Cycle
Gly2SerD	1 gly[e] \Rightarrow 1 ser_D[e]	Glycine to D-serine conversion
Glc2Lac	1 glc_D[e] \Rightarrow 2 lac_L[e]	Lactate production from Glucose
Glc2ATP	1 glc_D[e] \Rightarrow 36 atp[e]	ATP production from Glucose
Cys2GTHRD	1 cys_L[e] + 1 glu_L[c] + 1 gly[c] \Rightarrow 1 gthrd[e]	Catch of Cysteine to produce reduced Glutathione

140 Metabolic Scenarios

141 To test neuroprotective effects of tibolone during astrocytic metabolic inflammation we define
 142 three different metabolic scenarios. A ‘healthy’ scenario, where palmitate uptake rate was
 143 freely set by optimizer; an ‘inflamed’ scenario, where uptake rate of palmitate was forced
 144 to be stable in the mean of the half maximal inhibitory concentration (IC50) value for all
 145 objective functions included in table 1-1. IC50 values were calculated through a robustness
 146 analysis performed using uptake of palmitate (‘EX_hdca(e)’ in RECON 2.04) as control
 147 reaction and a 1000 points in the range from 0 to 1 mMgDW⁻¹h⁻¹ for each objective function.
 148 Uptake value where each objective function reached IC50 was selected and subsequently
 149 averaged. Finally, a medicated scenario, defined as an inflamed scenario that include
 150 279 reactions associated with tibolone and estradiol-derived compounds metabolism. Ten
 151 specific reactions described in table 1-2 associated to specific Tibolone action mechanism
 152 non included in RECON 2.04 were added to medicated scenario.

153 Metabolic Changes

Metabolic changes across metabolic scenarios were measured through two different approximations. Flux differences for each reaction between optimized scenarios were measured using the fold change calculated as described in equation 1-1.

$$foldChange = \frac{valueModel2 - valueModel1}{|valueModel1|} \quad (1-1)$$

Table 1-2: Set of reactions associated to tibolone specific action mechanism in brain reported by Kloosterboer, H. J. (2004) added to medicated scenario model.

ID	FORMULA REACTION	DESCRIPTION
T1	tibolone[e] \Leftrightarrow	Tibolone exchange reaction
T2	tibolone[e] \Leftrightarrow a3OHTibolone[e]	3 α hydroxytibolone interconversion
T3	tibolone[e] \Leftrightarrow b3OHTibolone[e]	3 β hydroxytibolone interconversion
T4	tibolone[e] \Rightarrow d4tibolone[e]	Δ -4Tibolone isomer formation
T5	b3OHTibolone[e] \Rightarrow d4tibolone[e]	Δ -4Tibolone isomer formation from 3 β -hydroxytibolone
T6	a3OHTibolone[e] \Rightarrow estradiol[c]	Estradiol receptor agonist action mechanism of 3 α -hydroxytibolone
T7	b3OHTibolone[e] \Rightarrow estradiol[c]	Estradiol receptor agonist action mechanism of 3 β -hydroxytibolone
T8	d4tibolone[e] \Rightarrow prgstrn[c] + tststerone[c]	Progesterone and androgen receptor activation by tibolone Δ^4 isomer
T9	a3OHTibolone[e] \Leftrightarrow a3SOTibolone[e]	3 α hydroxytibolone interconversion to sulfated inactive compounds
T10	a3SOTibolone[e] \Rightarrow	Tibolone inactive form in blood

154 Additionally, to obtain a full perspective about inflammation effects in metabolites pro-
155 duction, the production of each metabolite was set as objective function in each metabolic
156 scenario and differences were evaluated as well as flux differences.

157 **Proinflammatory, Antiinflammatory and Tibolone Action Mechanism**

158 **Associated Enzymes**

159 Identification of enzymes involved in proinflammatory and antiinflammatory responses as
160 well as in the tibolone action mechanism were identified through several sensitivity analysis
161 as follows: Proinflammatory enzymes, are those that catalyze reactions that being knocked
162 out allows an increase of objective function value. Antiinflammatory enzymes, are those
163 associated to reactions that being knocked out reduce even more the objective function
164 value. Tibolone action mechanism associated enzymes are those that catalyze reactions that
165 being knocked out inhibit entirely the metabolic effect of tibolone.
